BudgetBuddy Security Assessment

Security Audit to support four deliverables for the current BudgetBuddy app:

1. Conduct red teaming exercises for prompt injection, jailbreaks, and data leakage.
2. Provide concrete security safeguards for input validation, output filtering, and rate limiting.
3. Review API key handling and data privacy protections.
4. Document measures, test results, and known limitations.

Current Security Snapshot

Repository review for the current application shows:

- JWT bearer auth exists in `backend/auth.py` with username-only login.
- Pydantic request validation exists for selected payloads in `backend/main.py`.
- High-risk LLM endpoints include `/api/parse-expense`, `/api/chat`, `/api/agent/execute`, and `/api/parse-receipt`.
- Receipt uploads are checked for image or PDF types, but there is no explicit upload size cap in the API entrypoint.
- No dedicated rate-limiting middleware is present in the backend flow.
- No centralized output filtering or secret redaction layer is applied before model output is returned.
- The frontend env template still includes `VITE_GEMINI_API_KEY`, which would expose a model key to browser clients if used.
- Startup logs still reveal operational detail such as whether Supabase credentials are present.

This notebook treats the missing controls as remediation targets and documents them explicitly.

Red Team Plan

The exercises below target the main attack classes relevant to this application:

- Prompt injection against `/api/parse-expense`, `/api/chat`, and `/api/agent/execute`.
- Jailbreak attempts that request hidden instructions, secrets, or internal reasoning.
- Data leakage probes for API keys, JWT secrets, system prompts, database details, and other sensitive text.
- Validation checks for rejected content types on receipt upload.
- Lightweight abuse testing to show the current absence or presence of rate limiting.

Set `RUN_EXPENSIVE_LLM_TESTS=true` before running the notebook if you want live LLM endpoint tests to execute. By default, only low-cost validation and repository review cells run.

Reference Safeguards

These controls focus on three gaps identified during review:

- Input validation and upload bounds.
- Output filtering and redaction before returning model text.
- Rate limiting for public and LLM-backed endpoints.

Security Conclusions and Known Limitations

Expected conclusions after running this notebook:

- Input validation is present but incomplete. Length limits and typed schemas exist for some JSON bodies, yet upload size limits and injection-aware normalization are still missing.

Loading [MathJax]/extensions/Safe.js

- Authorization is enforced on sensitive endpoints, but the login model is intentionally lightweight and should be combined with rate limiting and monitoring in any real deployment.
- Prompt injection resilience depends heavily on model behavior because there is no dedicated pre-filter, policy engine, or output redaction layer.
- Data leakage risk is elevated by browser-visible key patterns in the frontend env template and by debug logs that disclose environment state.
- The current backend does not demonstrate an active 429 rate-limit control, so high-volume abuse remains a practical risk.

Known limitations of this notebook:

- Live LLM tests are optional because they consume quota and may create cost.
- Heuristic leakage detection can miss subtle disclosures or false-positive on benign text.
- This notebook documents and prototypes safeguards; it does not automatically patch the application code.
- True privacy assurance also depends on third-party providers, deployment config, transport security, database policies, and operational logging practices outside this notebook.

Recommended next action: integrate the reference safeguards into the FastAPI app, then rerun the red-team cells to capture before-and-after results in the same notebook.
